Abstract

Optimization of CO₂ Storage Capacity, Injectivity, and Storage Costs for Large-Scale CCS Deployment & Carbon Dioxide Removal Goals

By Edna Rodriguez Calzado

Large-scale deployment (i.e. US-wide) of Carbon Capture and Storage (CCS) technology will play a key role in carbon storage removal (CDR) and overall climate mitigation efforts. The economic feasibility of large-scale CCS deployments largely depends on the CO₂ storage costs per project, including capture, transport, and storage. However, the suitability of regional storage and injectivity per project, particularly for large-scale purposes, is not well understood.

This study focuses on two concepts that enhance our understanding of regional storage and injectivity throughout the U.S. The first concept focuses on identifying all potential areas for CO₂ storage within the sedimentary rocks throughout the U.S. based on a novel concept we call the CO₂ Storage Window. The second concept focuses on optimizing CO₂ storage costs by considering the area extent from the pressure built-up caused by CO₂ injection. This area extent is a novel concept we call Pressure Space. Understanding the pressure space of a project helps delineate the area of review for a project and the extent of the pore space required for the project.

The results of this study include a spatial geodatabase and a series of U.S. cohesive, spatial distribution maps showcasing 1) CO₂ storage potential in areas not explored before, 2) cumulative storage capacity per unit area (km²), 3) injectivity and number of injection wells needed to inject 1 million tons (MMT) of CO₂ a year, 4) Storage costs per CCS project and storage costs per ton of CO₂, assuming a constant maximum storage capacity of 20 MMT per project over a 20 year timeframe. The number of wells per project range from 1 to 19, while storage costs per ton of CO₂ range from $4.7 to $51.7 per ton of CO₂ (P10 to P90 range).
